Abstract. In this paper we analyse an M1.0 confined flare observed mainly during its gradual phase. We used the data taken during a coordinated observational campaign between ground based instruments (THEMIS and VTT) and space observatories (SoHO/CDS and MDI, TRACE and RHESSI). We use these multi–wavelength observations to study the morphology and evolution of the flare, to analyse its gradual phase and to understand the role of various heating mechanisms. During the flare, RHESSI observed emission only within 3 – 25 keV spectral range. The RHESSI spectra indicate that the emission of the flare was mainly of thermal origin with a small non–thermal component observed between 10 and 20 keV. The temperature of plasma obtained from the fitting of the RHESSI X–ray spectra was between 8.5 and 14 MK. The lower temperature limit is typical for a plasma contained in post flare loops observed in X–rays. Higher temperatures were observed during a secondary peak of emission corresponding to a small impulsive event. The SoHO/CDS observations performed in EUV Fe XIX line also confirm the presence of a hot plasma at temperatures similar to those obtained from RHESSI spectra. Besides, the EUV structures were located at the same place as RHESSI X–ray emission. The magnetic topology analysis of the AR coming from a linear force–free field extrapolation explains the observed features of the gradual phase of the flare i.e. the asymmetry of the ribbons and their fast propagation. The combination of the multi–wavelength observations with the magnetic model further suggests that the onset of the flare would be due to the reconnection of an emerging flux in a sheared magnetic configuration.

Key words. Sun: flares – Sun: X-rays – Sun: magnetic fields

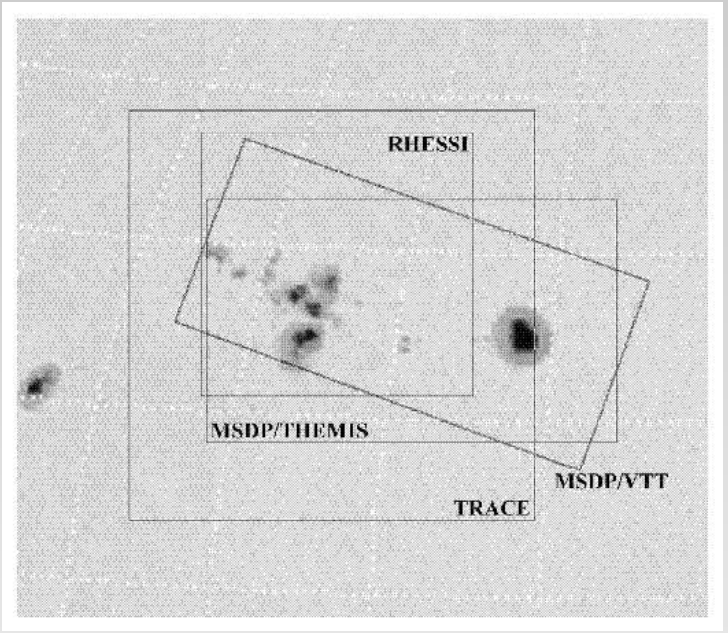
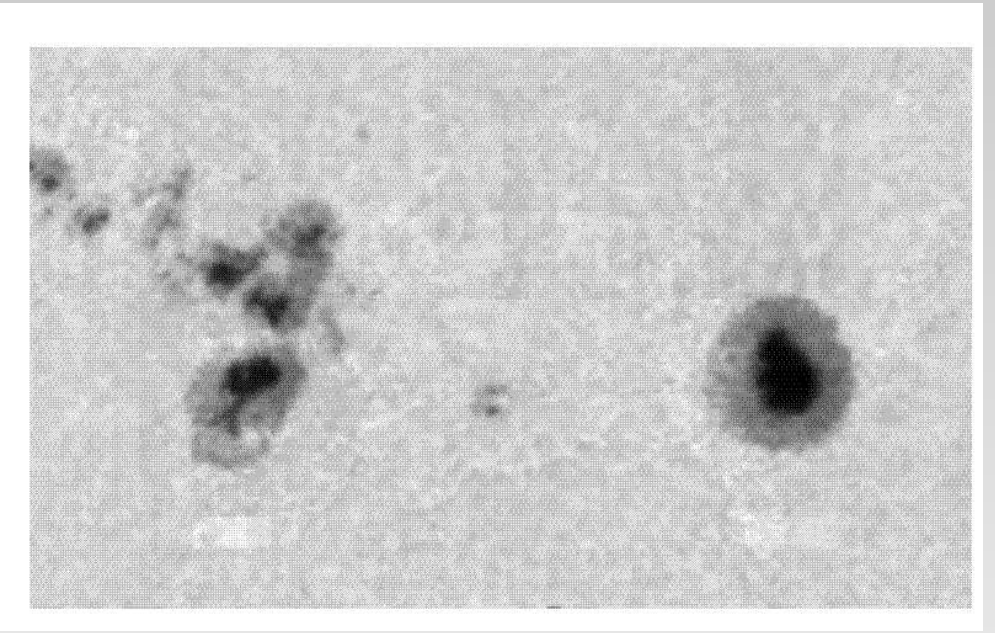
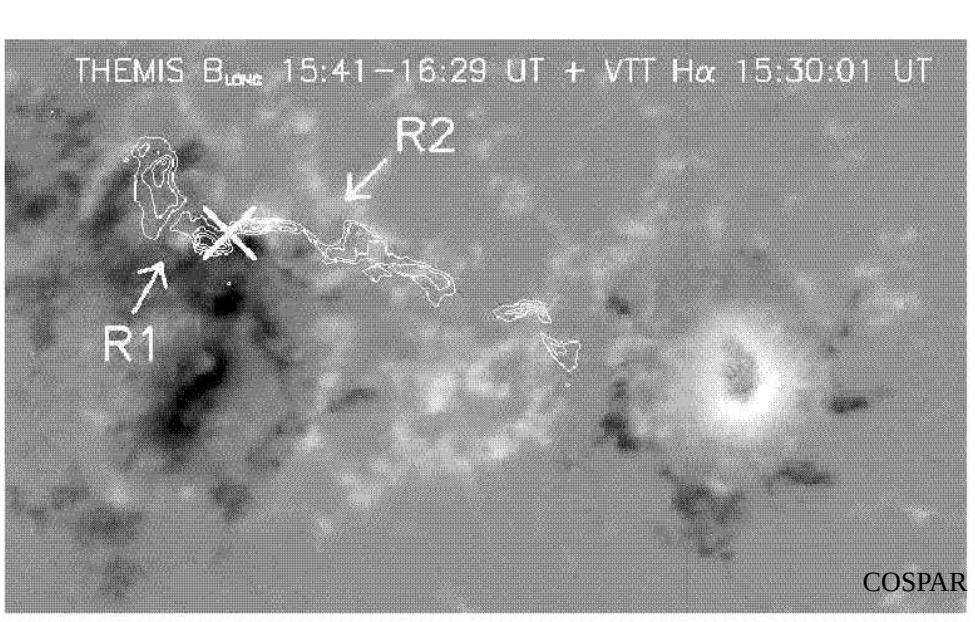
Overview I

UNIVERSITY OF CAMBRIDGE







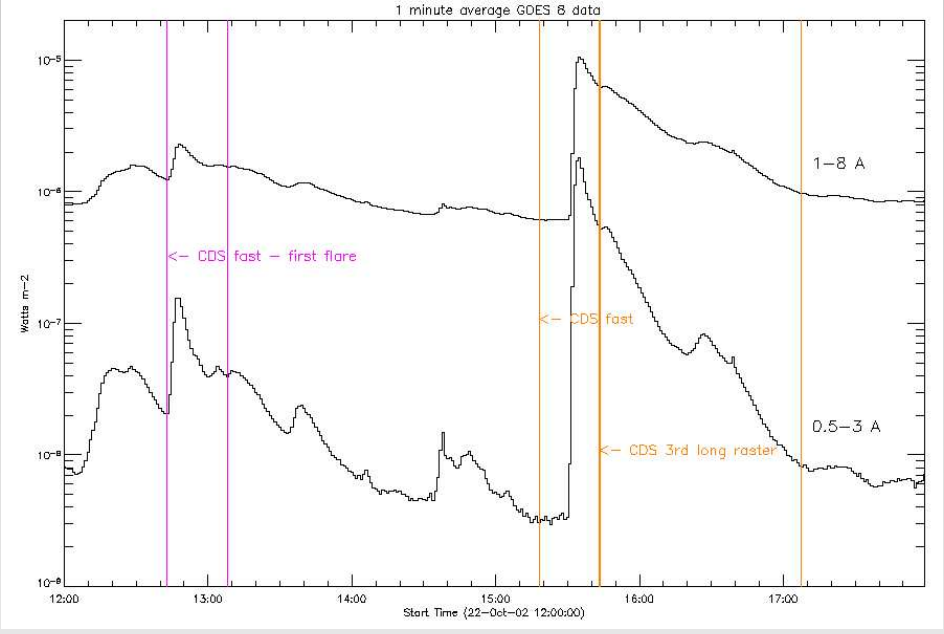
Overview II

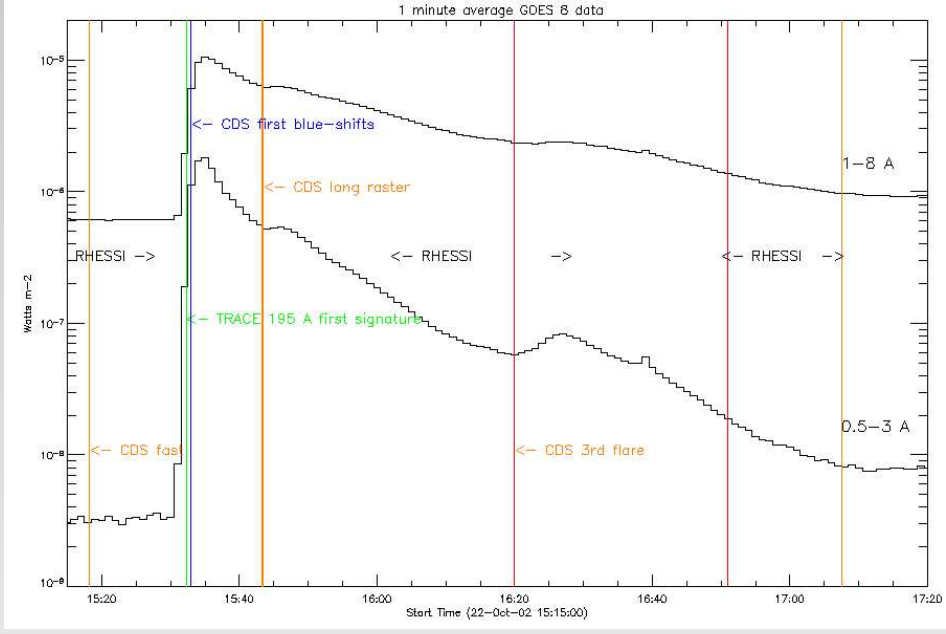
UNIVERSITY OF CAMBRIDGE

- THEMIS observed continuously between 15:41–17:26 UT.
- TRACE and VTT/MSDP observations were performed during the whole flare.
- VTT/MSDP observations in Hα 9 scans between 15:30 and 16:17 UT
- TRACE high cadence (40 s) in the 195 Å band between 15:29 and 15:41 UT

Overview III - GOES

UNIVERSITY OF CAMBRIDGE





RHESSI

UNIVERSITY OF CAMBRIDGE

RHESSI counts rates (the 12–25 keV band are multiplied by a factor of 10).

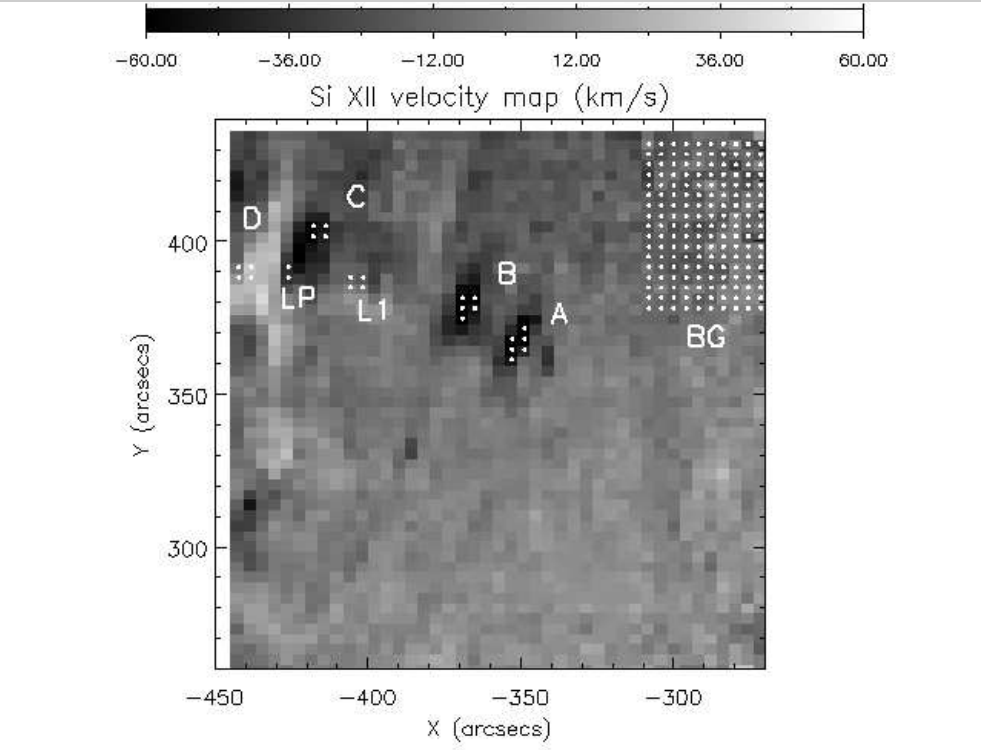
The Fe XIX case

UNIVERSITY OF CAMBRIDGE

Our calibration, based on this small sample, provides a wavelength of 592.16 Å, in excellent agreement with Skylab measurements.
Lawson & Peackok (1980) reviewed $n = 2 \rightarrow n = 2$ transitions, and suggested an energy for the 2s 2 2p 4 $^1D_2$ level of 168770 cm^{-1}.
$\rightarrow \lambda = 592.522$ Å
$\rightarrow$ the considerable difference of 183. km/s compared to our result.

Selected areas

UNIVERSITY OF CAMBRIDGE



Si XII velocity map, with the areas selected for further analysis. Areas A,B,C correspond to regions of strong blue-shifts, while area D of red-shift. Region LP corresponds to the area of peak Fe XIX intensity, while region L1 is where the central part of the flare loop is located. Region BG is a ‘background’ reference region.

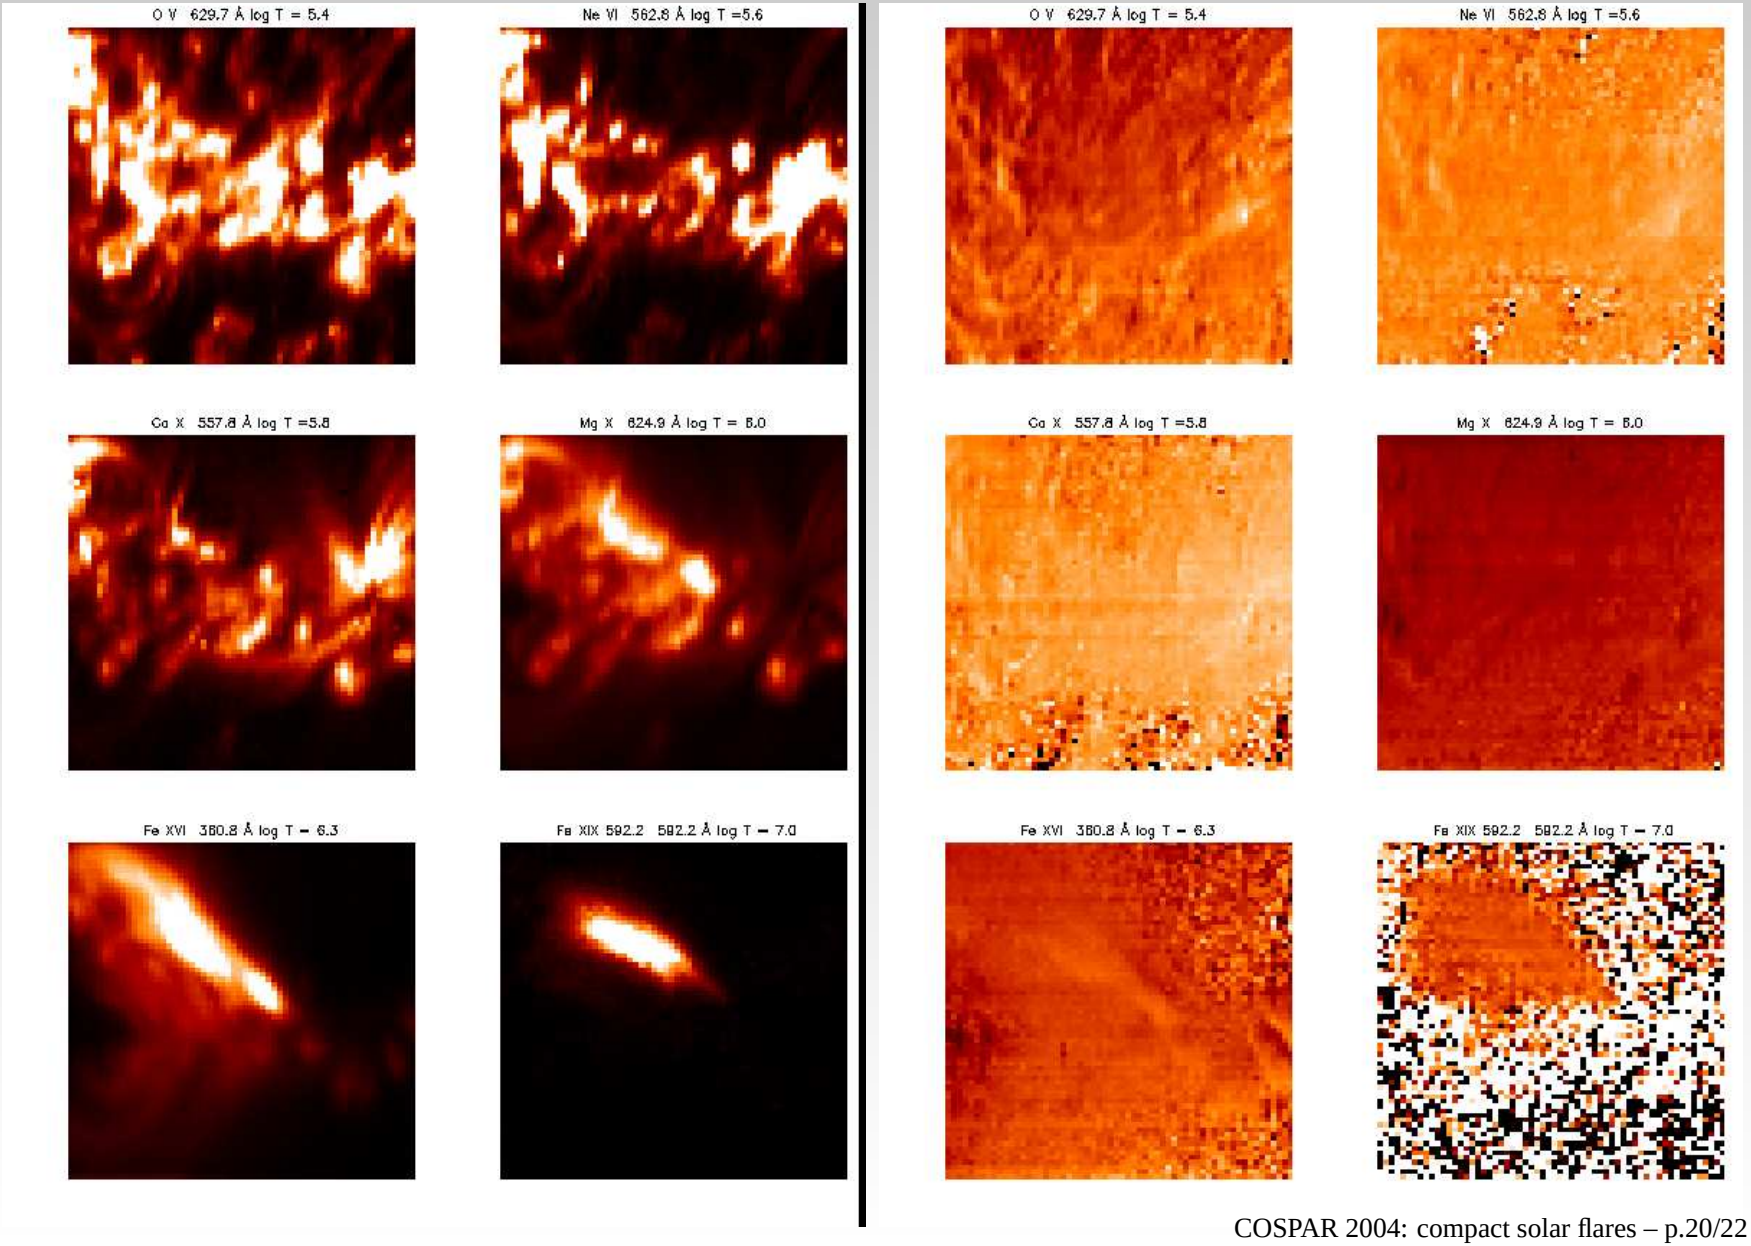
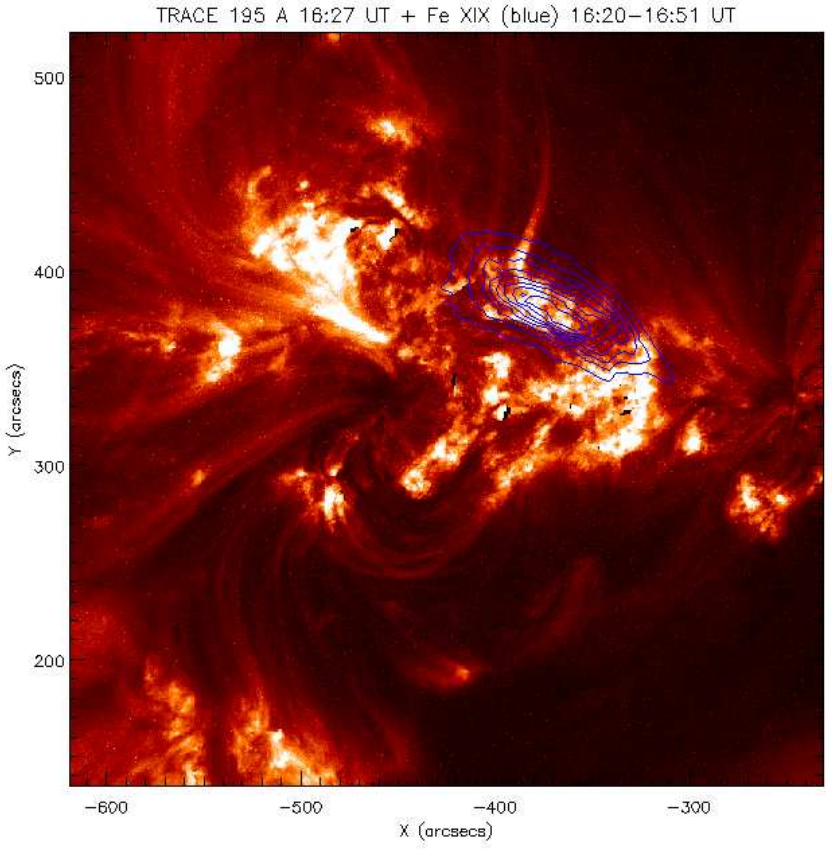
Post-flare CDS raster 15:43–17:07 UT

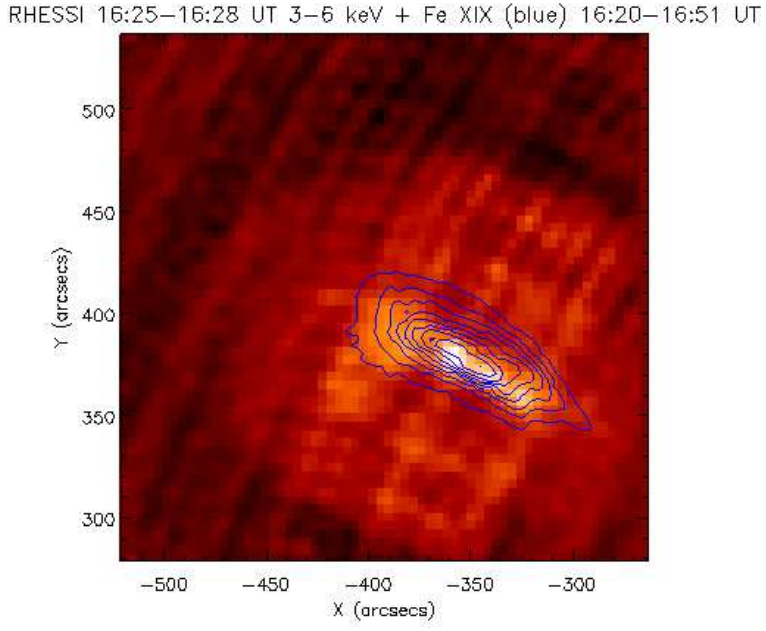
UNIVERSITY OF CAMBRIDGE



Post-flare CDS raster – II

UNIVERSITY OF CAMBRIDGE





Summary of preliminary results

UNIVERSITY OF CAMBRIDGE

- Strong blue-shifts in lines emitted in the 1-8 MK range are observed at the bases of hot Fe XIX structures.
- The hot structures are also clearly visible in the TRACE 195 Å band
- The hot structures match the thermal emission as seen by RHESSI
- The peak Fe XIX emission, recorded between 15:35 and 15:43 UT, occurred just above the region of strong mixed polarity.
- The TRACE 195 Å emission is co-spatial with the CDS Fe XIX emission, which suggests that the bulk of the TRACE 195 Å emission at the flare site is due to Fe XXIV.
- Transition region densities can be estimated using O IV.
